Chest pain

Cardiac chest pain

Acute

- Acute coronary syndromes
- Acute aortic syndromes
- Myocarditis
- Pericarditis
- Pulmonary embolism
- Pleuritis

Chronic / recurrent

- Chronic coronary syndromes - angina
- Aortic stenosis
- Hypertrophic cardiomyopathy
- Aortic aneurysm
- Pericarditis

Acute coronary syndromes

Clinical

Chest pain
Dyspnea
Palpitations
Vegetative signs

ECG

Biochemical

Hs- Troponin I / T
Myoglobin
CK-MB

ACS classification

Types of myocardial infarction

Myocardial Infarction Type 1

Plaque rupture/erosion with occlusive thrombus

Plaque rupture/erosion with non-occlusive thrombus

Myocardial Infarction Type 2

Atherosclerosis and oxygen supply/demand imbalance

Vasospasm or coronary microvascular dysfunction

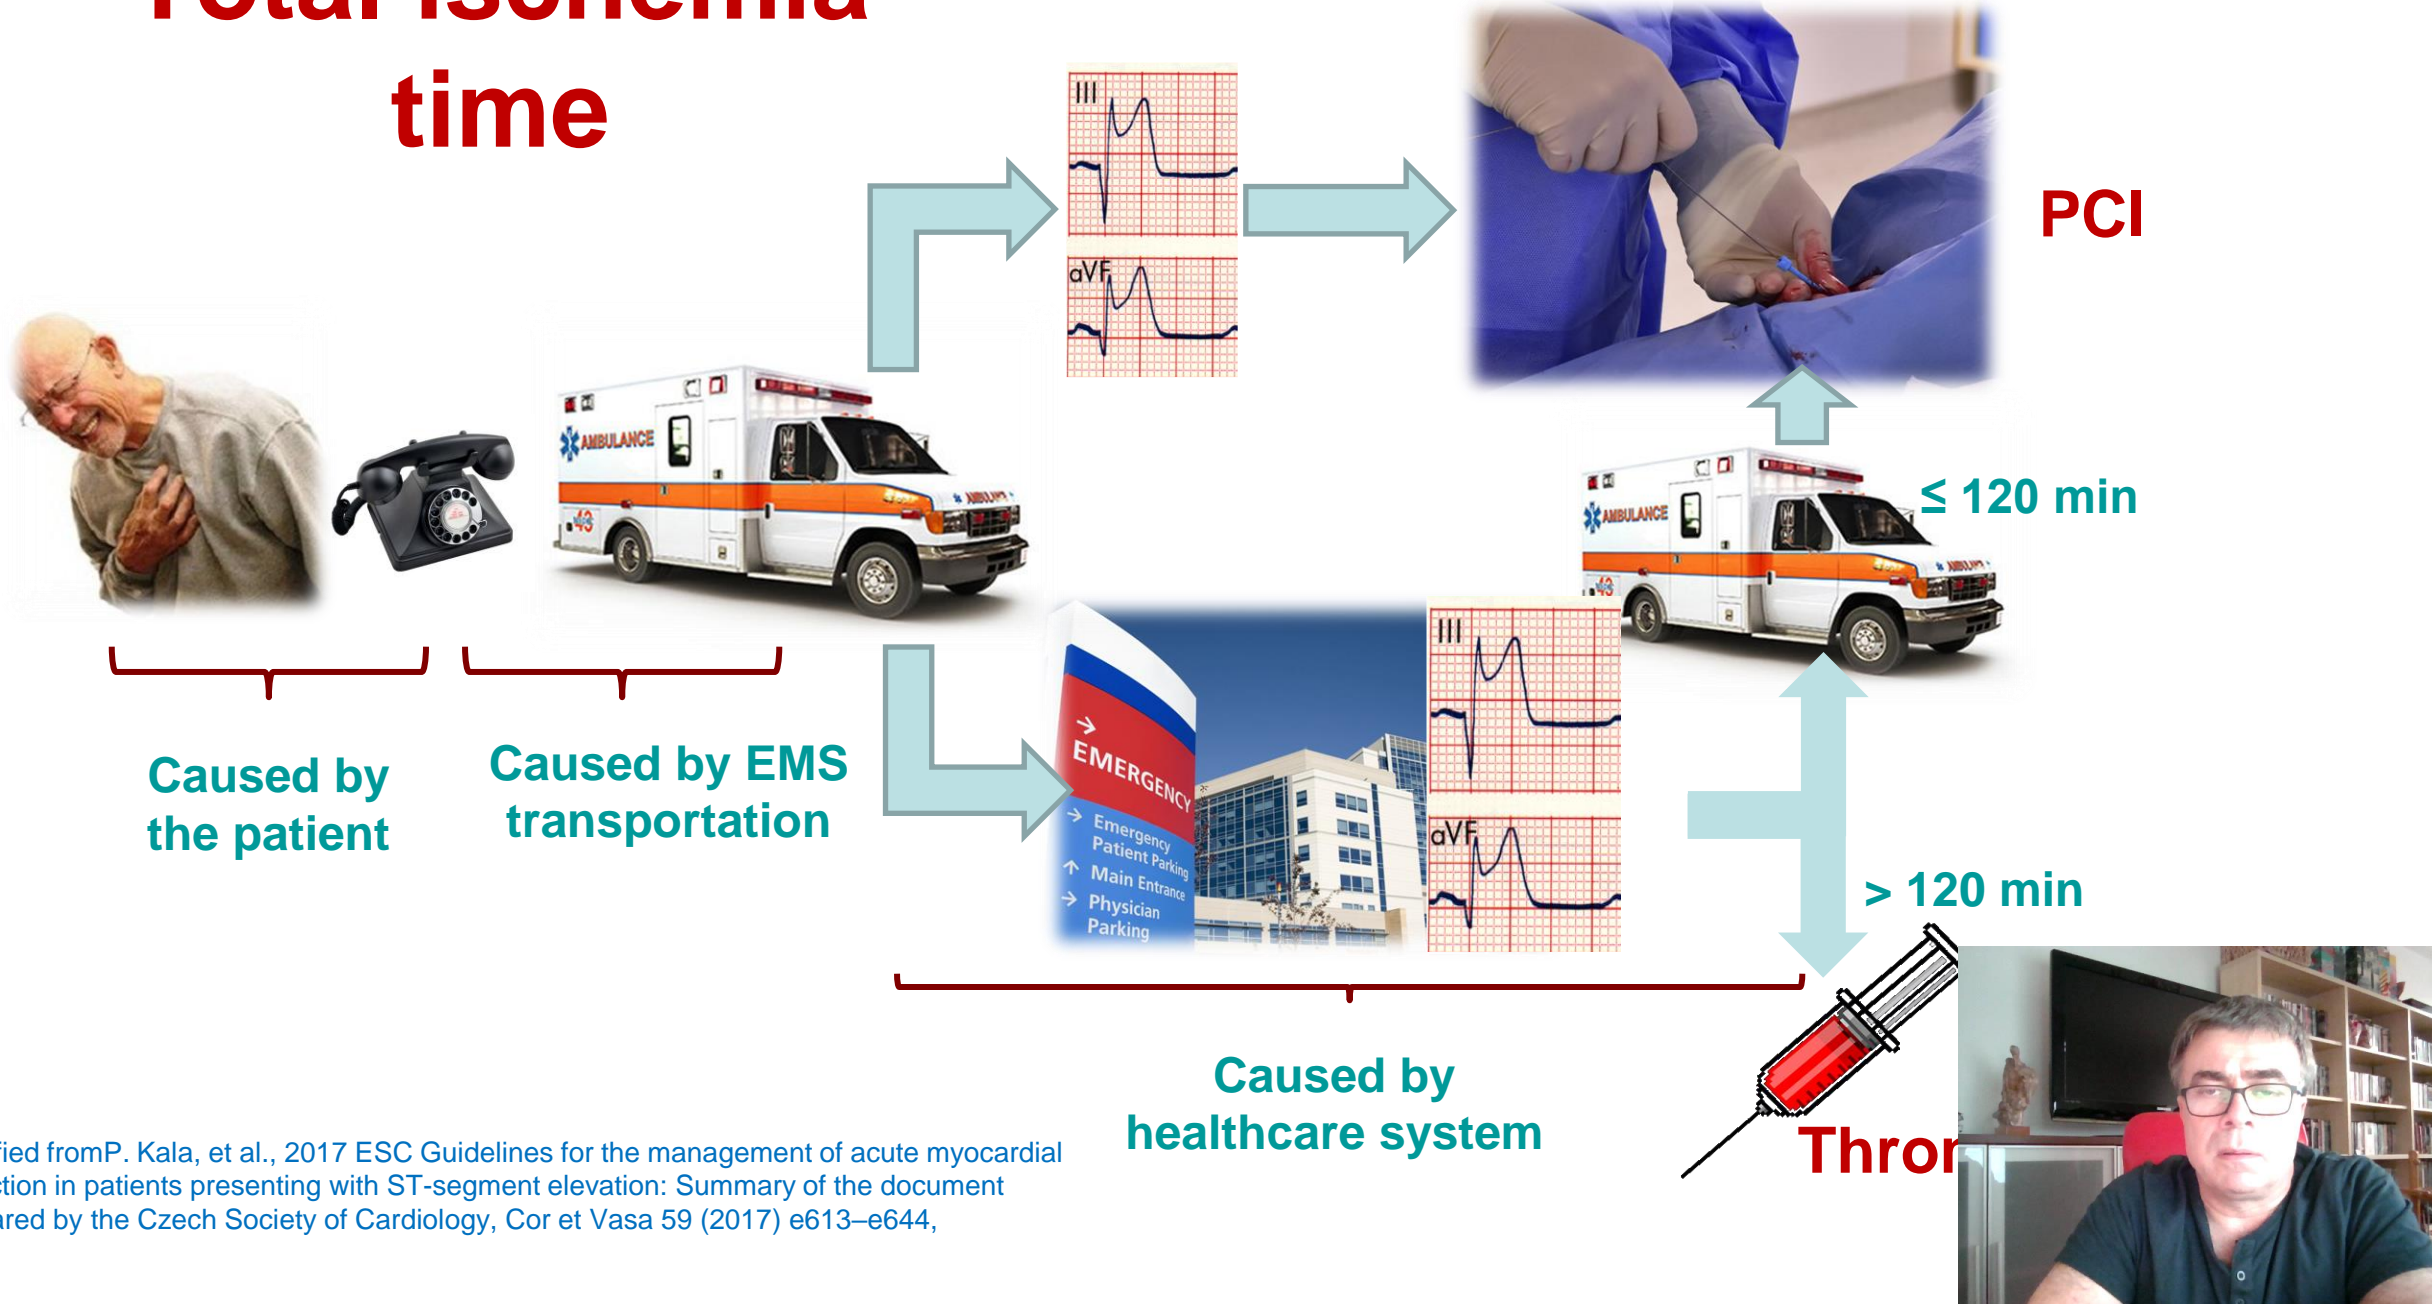

Non-atherosclerotic coronary dissection

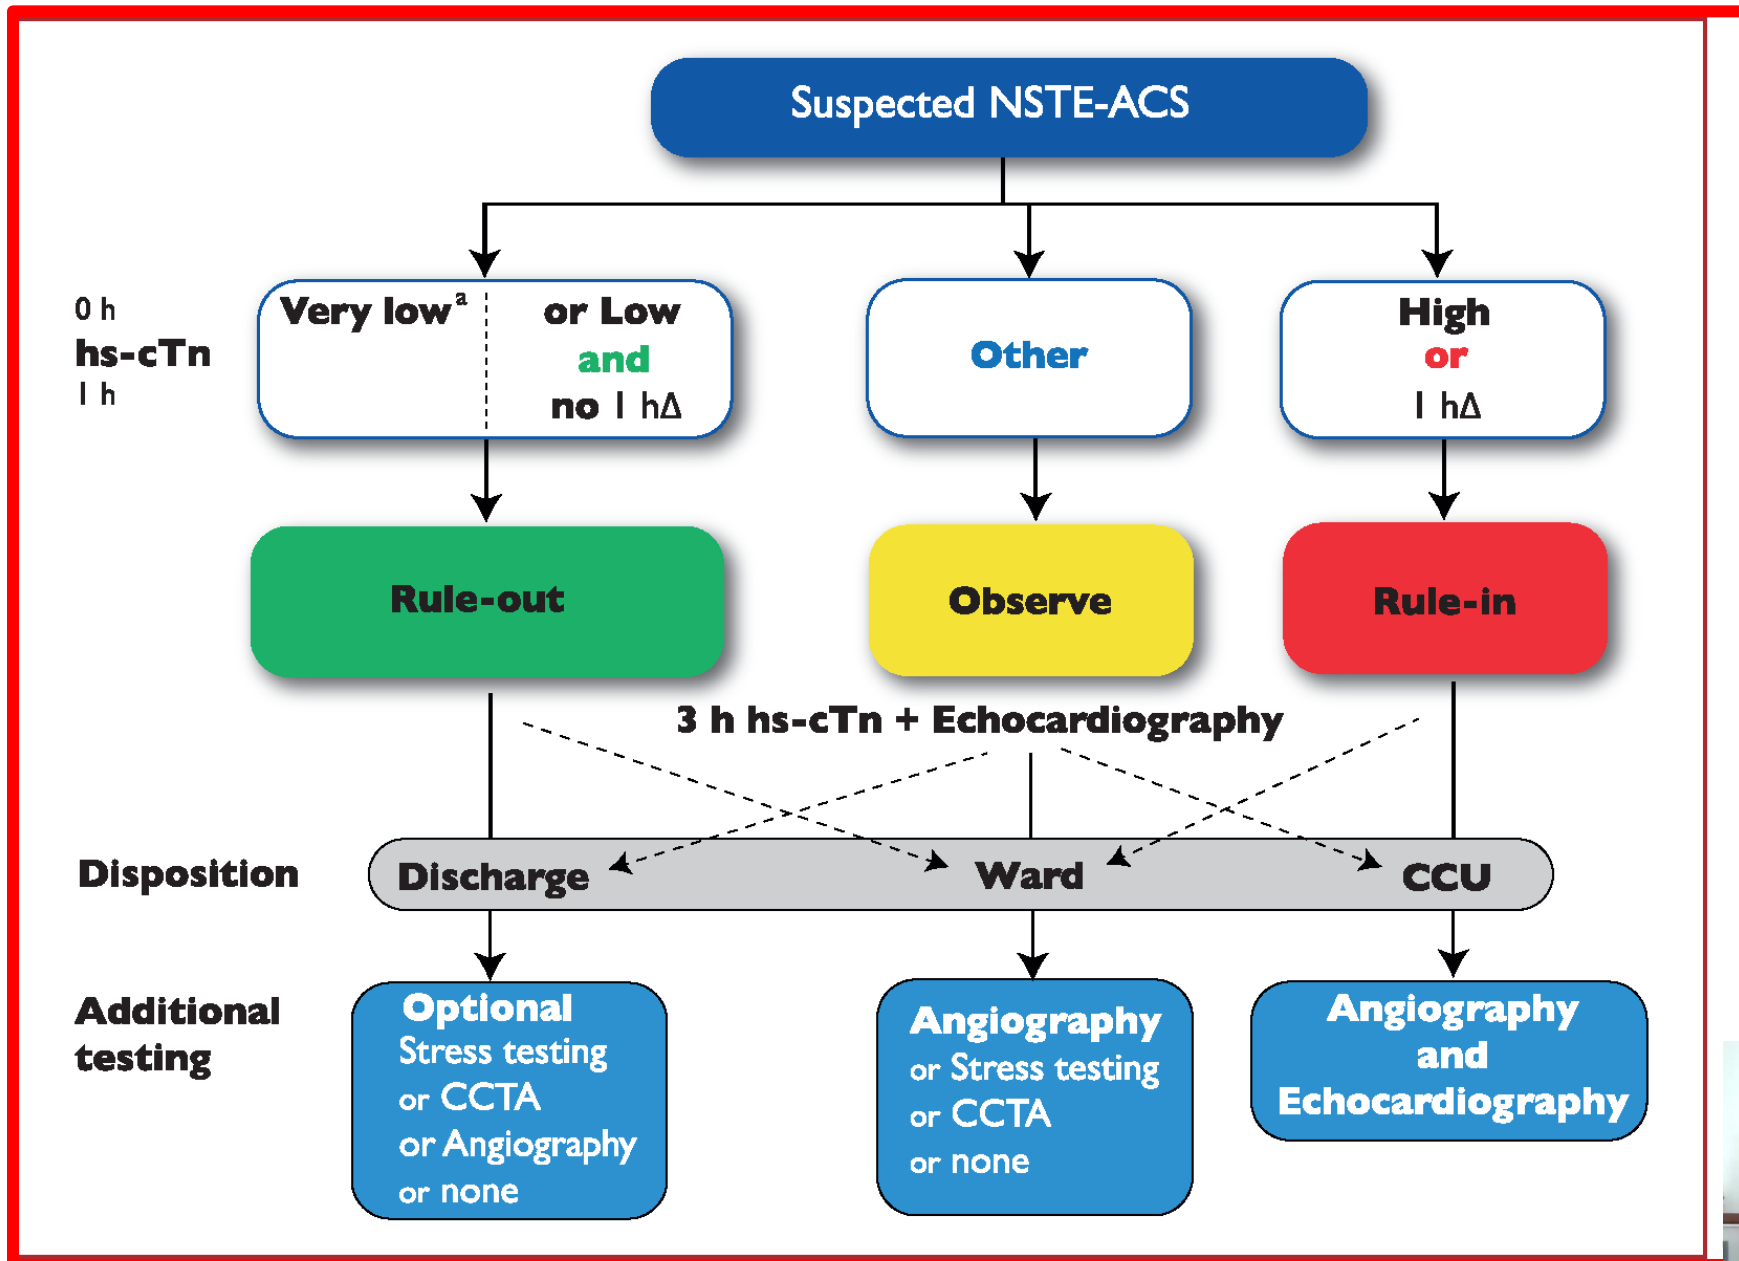

Oxygen supply/demand imbalance

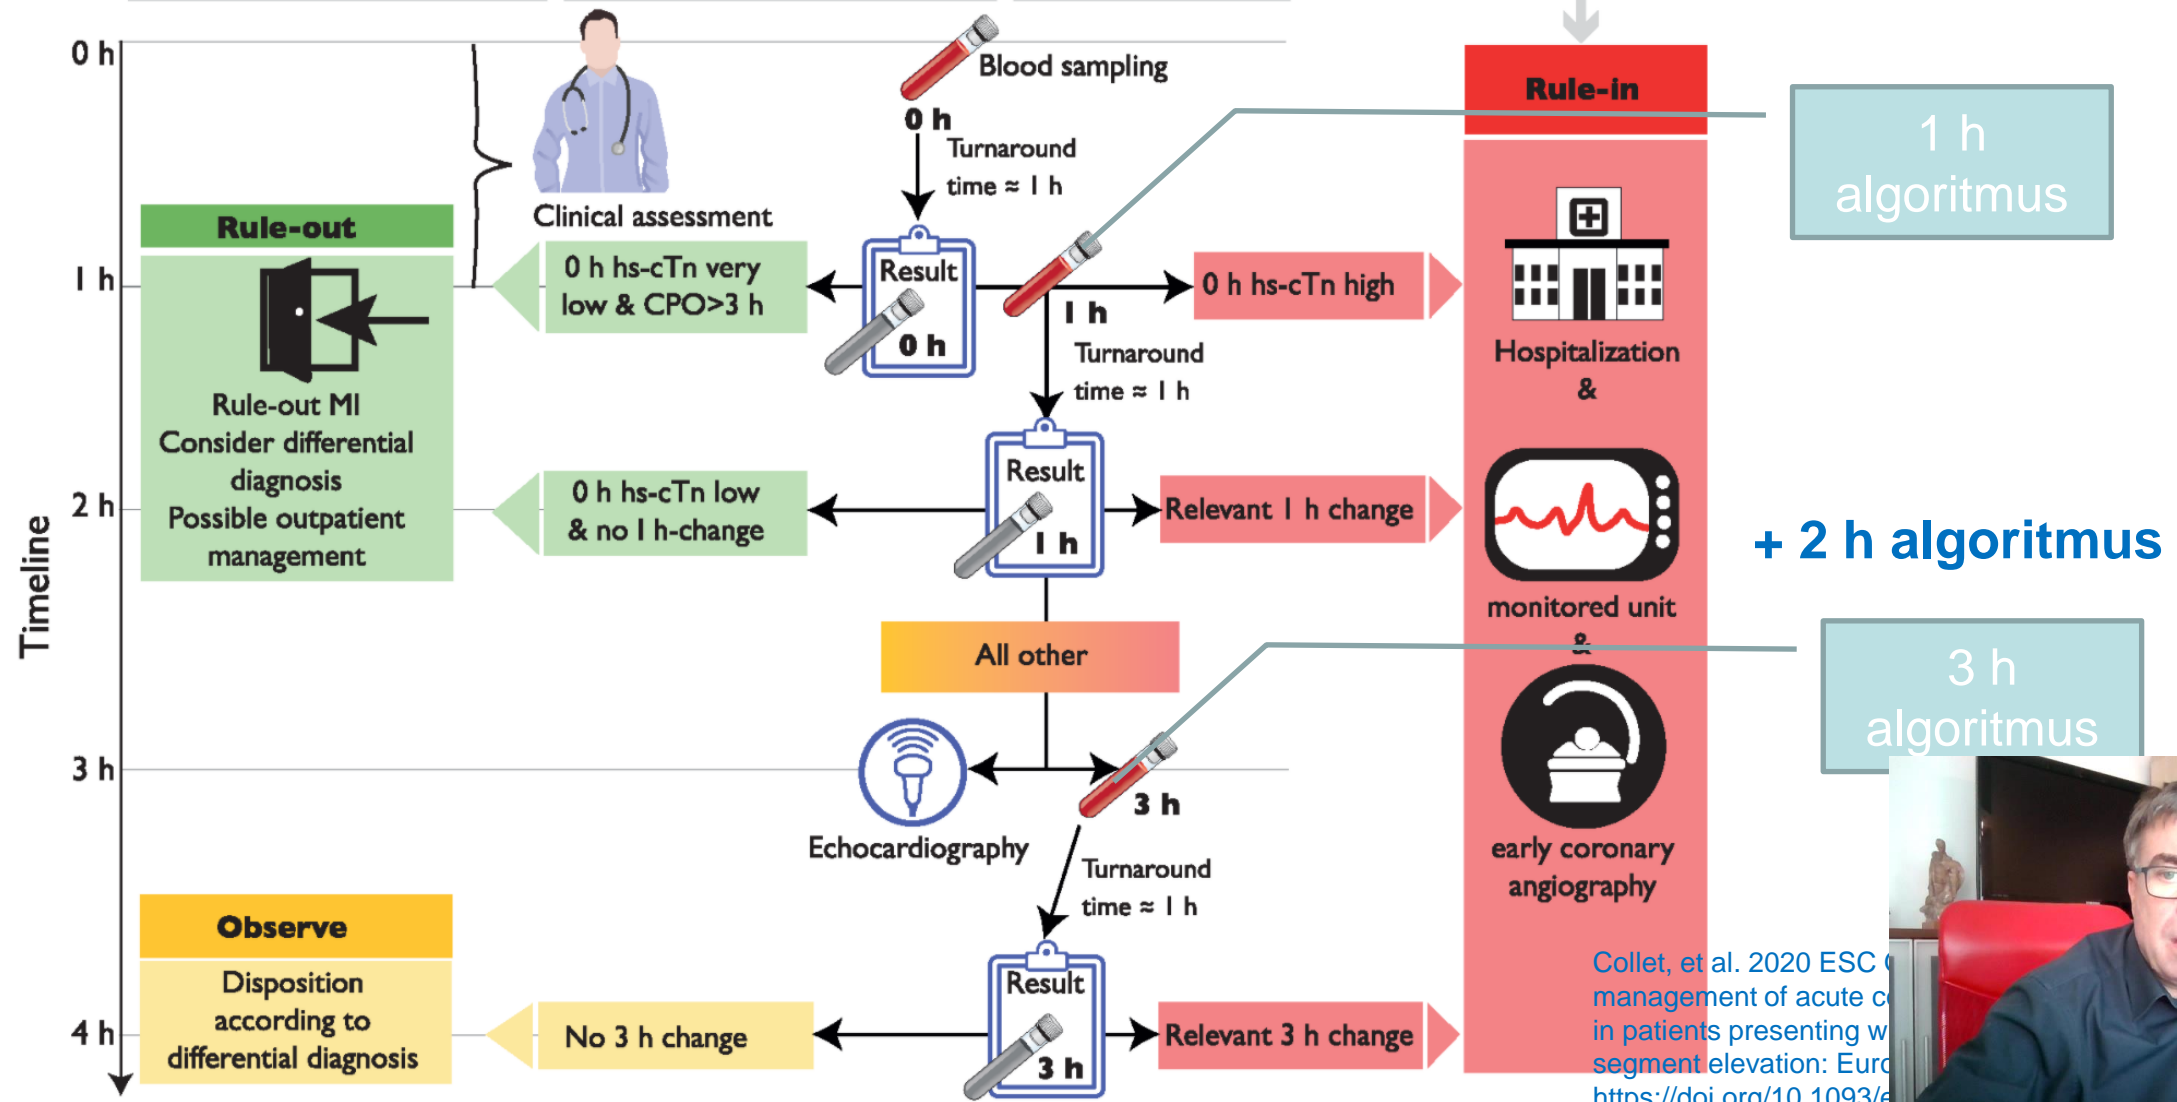

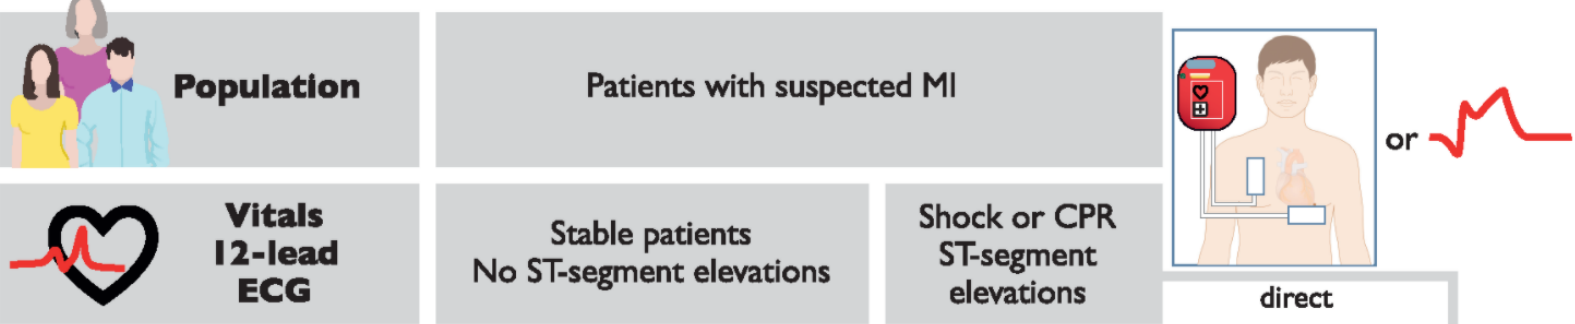

Total ischemia time

Modified from P. Kala, et al., 2017 ESC Guidelines for the management of acute myocardial infarction in patients presenting with ST-segment elevation: Summary of the document prepared by the Czech Society of Cardiology, Cor et Vasa 59 (2017) e613–e644,

Acute aortic syndromes

Dissection

Penetrating ulcer

**Intramural
hematoma**

Traditional classification of aortic dissection

- Acute < 14 days
- Subacute 15-90 days
- Chronic > 90 days

De Baakey

Type I

Type II

Type III

Stanford

Type A

Type A

T

Jiang et al. American Journal of Translational Research (2016)
Erbel et al. European Heart Journal (2014) 35:2873–2926

Dissection

~ 70 – 80%

A: 60%

B: 40%

Penetrating ulcer

2 - 7%

A: 5%

B: 95%

**Intramural
hematoma**

10 - 25%

A: 30%

B: 70%

Diagnostic methods in diseases of the aorta

- Risk factors
 - History
 - Genetic syndromes and gene sequencing
- Imaging methods
 - Chest X-ray
 - Echocardiography – TTE a TEE
 - CT angiography
 - Angiography
 - MRI
 - IVUS
 - PET - CT
- Biochemic markers (D-dimers, CRP, sELAF, calponin, smMHC)

Differential diagnosis of acute chest pain

Acute coronary syndromes

- ECG – seek ST elevations or deep depression in precordial leads – STEMI = no need to wait for troponin results
- Troponin – use HS-TnI or HS-TnT – check the level and dynamic changes – progressive elevation after 1,2 or 3 hours
- Coronary angiography (invasive or CT) – CT scan only if in doubts and in low-risk patients, if suspicion is high, use invasive approach

Aortic dissection

- Echocardiography – Transoesophageal more useful, seek for intimal flap
- CT angiography – very useful
- MRI – takes time, less available
- D-dimers – may be elevated similar to pulmonary embolism cases – absence does not exclude acute aortic syndrome

Pulmonary embolism

- ECG – not very specific
- Echocardiography – seek right ventricular overload (dilatation, dysfunction) and signs of pulmonary hypertension
- CT angiography – method of choice, be sure that the patient is stable enough to go through the scan,
- Ventilation / perfusion scan – useful but takes more time than CT, not widely available, use rather for CTEPH diagnosis
- D-dimers – low levels – low probability of PE, do not use to confirm the diagnosis

Pericarditis

- ECG – not very specific (PR depressions, repolarization changes)
- Lab. Markers of inflammation (CRP, procalcitonin, WBC)
- Echocardiography (seeks pericardial effusion, pericarditis may be present even in absence of any effusion)
- Exclude acute coronary syndromes (try not to label even young patients as pericarditis before being sure ACS is excluded)
- MRI or PET-CT may be helpful

Acute myocarditis

- Exclude acute coronary syndrome – troponins may be positive – usually with moderate dynamic changes!!! Use imaging.
- ECG, Echocardiography – non specific changes
- Lab. Markers of inflammation
- MRI – most useful method for myocarditis diagnosis – seek edema, accumulation of gadolinium (LGE – late gadolinium enhancement)
- Endomyocardial biopsy
